[57] **ABSTRACT**

A data transmission technique referred to herein as
 Dynamic Time Division Multiplexing (DTDM) is dis-
 closed along with a set of multiplexers and demultiplex-
 ers required to apply DTDM in an actual telecommuni-
 cations network. The DTDM technique uses a transmis-
 sion format which is compatible with the existing digital
 circuit transmission format and the packet transmission
 format so that DTDM is able to handle the transmission
 of circuit and packet traffic. Thus, DTDM provides a
 flexible migration strategy between present circuit net-
 works and future broadband packet networks.

FIELD OF THE INVENTION

This invention relates to the transmission of data in telecommunications networks. More particularly, the present invention relates to a data transmission technique referred to herein as Dynamic Time Division Multiplexing (DTDM), and a set of multiplexers and demultiplexers required to apply DTDM in an actual telecommunications network. DTDM is capable of effectively handling both circuit and packet traffic and thus provides a migration strategy between the present circuit switched telephone network and the future broadband packet switched network.

BACKGROUND OF THE INVENTION

Presently, there are significant uncertainties when it comes to predicting the future demand for broadband telecommunications services such as high definition video and interactive data communications. This uncertainty in the future demand for broadband telecommunications services has a significant impact on the design of public telephone networks. First, to satisfy the unknown growth pattern in future service demands, it is desirable to have a robust network design that can be easily modified in response to changes in demand for particular telecommunications services. Second, the network must be able to handle vastly different types of traffic ranging from low speed data and voice to full motion video. Third, depending on the demand for wideband services, a network design must be capable of providing a migration strategy from existing copper wires and circuit transmission and switching facilities to optical fibers and the succeeding generations of high speed packet transmission and switching facilities, which packet facilities are used in connection with the delivery of wideband telecommunications services. These three criteria determine the selection of the three major components of a network design: network topology, transmission systems and switching systems. Here, the concern is primarily with transmission systems and transmission techniques which meet the foregoing criteria.

Two important types of commercially used transmission systems are circuit systems and packet systems. Typically, circuit systems utilize time division multiplexing (TDM) as a transmission technique. When

2

TDM is used, each data stream comprises frames which are subdivided into slots. Corresponding slots in each frame are allocated to specific connections. For example, the first slot in each frame is allocated to one specific connection and the second slot in each frame is allocated to a second connection, etc. Each frame also includes a field which contains transmission overhead information including frame synchronization words and control words. This traditional circuit transmission format can be extended to multiple bit rate services by allocating multiple slots in each frame to high bandwidth services. In such circuit transmission systems, a combination of space division switching and time division switching is utilized at the network switches to swap time slots between various bit streams so that connections to and between specific subscribers are established.

Historically, the first digital circuit transmission systems were introduced during the 1960's. These first digital circuit transmission systems were introduced in inter-office trunking applications to carry 24 voice channels by a single 1.544 Mb/sec digital stream. This is known as the DS-1 signal. Subsequently, the wide deployment of digital channel banks in the public telephone network required the multiplexing of several DS-1 signals into a higher speed bit stream to efficiently utilize available transmission links. As the network grew further, continuing efforts to effectively multiplex tributaries having different bit rates into a common bit stream resulted in the well-known hierarchical multiplexing plan comprising the DS-1 (1.544 Mb/sec), DS-1C (3.152 Mb/sec), DS-2 (6.312 Mbit/sec), DS-3 (44.736 Mb/sec) and DS4 274.176 Mb/sec signals.

Conventional circuit transmission systems suffer from a number of shortcomings. Perhaps the most important problem is the multiplexing hierarchy itself. An important result of the hierarchy is an inherent lack of flexibility. Since the network can only transmit the set of signals in the hierarchy, every telecommunications service has to meet the stringent interface requirement of given hierarchical signal bit rates, instead of the particular service being able to transmit at its own natural bit rate. Therefore, the packet mode of transmission which is inherently bit rate flexible is favored for future broadband networks which are to be adapted to deliver enhanced telecommunication services such as high definition video and interactive data communications.

In contrast with circuit transmission systems which transmit data in frames subdivided into slots, packet transmission systems transmit data in discrete blocks or packets, with each packet having an address header at the front thereof. At the network switches, packets are routed from a specific input line to a specific output line, based on address information contained in the packet header. In this way data packets can be routed from a particular subscriber location, through a telecommunications network, to another subscriber location. Packet transmission techniques and especially fast packet transmission techniques (see e.g., R. W. Muise et al., "Experiments in Wideband Packet Technology", Proc 1986 International Zurich Seminar on Digital Communications, pp. 136-138 are inherently bandwidth flexible (i.e. the number of packets generated by a given service per unit time is flexible) and thus are suitable for wideband enhanced communications services. Accordingly, it is desirable to introduce packet transmission technology

LU 0000933

4,893,306

3

into the public telephone network, which up to now is based primarily on circuit transmission technology.

The commonly-held view as to how to introduce packet technology into the public network is to deploy a packet overlay network because the existing network is optimized for circuit transmission and is therefore incompatible with packet transmission techniques. Accordingly, many deployment strategies recommend constructing an overlay packet network for a set of wideband services and hope that the migration of new services to the packet overlay network will allow the existing circuit transmission network to be phased out slowly. The main advantage of a packet overlay network is the quick realization of an end-to-end network for new services. However, the approach requires a large initial capital investment and increases operational cost by requiring the management of multiple separate networks.

It is an object of the present invention to provide an alternate approach for introducing packet transmission technology into the public telephone network, which approach requires the replacement of existing transmission components but not the implementation of an entirely new network. Thus, it is an object of the invention to provide a digital data transmission system capable of handling both existing hierarchical circuit traffic and packet traffic.

With regard to the above-identified objects of the invention, it should be noted that recent advances in network switch designs have blurred the distinction between packet networks and circuit networks. A typical switch for use in a telecommunications network has three major components: control processor, switch interfaces, and interconnection network. The control processor handles call set-up and tear-down, maintenance and administrative functions. The switch interfaces convert transmission formats (i.e., the format data has when transmitted between switching nodes) to switch formats (i.e., the format data has when processed within switching nodes). The interconnection network routes information blocks from specific input lines to specific output lines of the switch. For the existing digital circuit systems used in the public telephone network, the information in a specific time slot on an incoming line is transferred, via the switch, to a specific time slot on an outgoing line. Thus, the interconnection network serves as a crossconnect for the incoming signals on a slot-by-slot basis.

It has recently been shown (see e.g., Day-Giacopelli-Huang-Wu, U.S. patent application Ser. No. 021,664 entitled Time Division Circuit Switch, filed on Mar. 4, 1987, now U.S. Pat. No. 4,782,474, issued Nov. 1, 1988, and assigned to the assignee hereof) that a switch for use in a circuit network can be built using a self-routing packet interconnection network. An example of such a self-routing packet network is the Batcher-banyan network. Based on the address headers associated with fixed sized packets, the Batcher-banyan network routes a plurality of packets in parallel to specific destination addresses (i.e., specific output lines) without internal collisions. Thus, to mimic the operation of the conventional time-space-time switches used in circuit networks, switch interfaces are provided which perform the time slot interchange function and which are able to insert headers in front of circuit slots to convert such slots into packets for routing through the self-routing interconnection network and able to remove headers from packets leaving the self-routing interconnection

4

network to reconvert packets back into conventional circuit time-slot format.

In addition to circuit and packet transmission, another mode of digital transmission is known as Asynchronous Time Division Multiplexing (ATDM). See e.g., W. W. Chu "A Study of Asynchronous Time Division Multiplexing for Time Sharing Computer Systems" Proc AFIPS Vol 35, pp. 669-678, 1969 and A. Thomas et al. "Asynchronous Time Division Techniques: An Experimental Packet Network Integrating Video Communication" Proc International Switching Symposium, May 1984. ATDM is used in connection with continuous and bursty data traffic. ATDM uses channel identifiers with actual data to allow on-demand multiplexing of data from subscriber terminals with low channel utilization. The channel identifiers and associated data form time slots. However, ATDM is bit rate flexible since the appearance of packets can be asynchronous. Slot timing is obtained from a special synchronization pattern which is inserted into unused time slots. Since the synchronization pattern appears only in unused time slots, ATDM cannot be used to carry existing high speed hierarchical signals wherein the loading is close to one hundred percent.

In short, the situation is that the present public telephone network utilizes circuit transmission technology and the associated time division multiplexing transmission techniques, while future broadband services, the demand for which is presently uncertain, are best offered using packet transmission technology. It is therefore an object of the invention to provide a transmission system which is capable of integrating present circuit traffic with future packet traffic so as to provide a flexible migration strategy from the existing copper wire based circuit network to succeeding generations of high bandwidth packet transmission networks.

SUMMARY OF THE INVENTION

The digital network transport system of the present invention, referred to herein as Dynamic Time Division Multiplexing (DTDM), is a flexible network transport system capable of effectively handling both circuit and packet traffic. By combining conventional time division multiplexing techniques and packet transmission techniques, DTDM enables a flexible transition from the existing circuit type networks to future broadband packet transmission networks.

In a network utilizing DTDM, each transmission bit stream is divided into frames. These frames are the fundamental unit of data transport in DTDM. Each such frame comprises two fixed length fields: overhead and payload. The overhead field includes, for example, a frame alignment word for frame timing and the empty/full status of the frame. The payload field of each frame may be filled with a data packet including header or a slot from a circuit transmission stream. Before a slot from a circuit transmission stream can be inserted into the payload field of a DTDM frame, it must first be converted into a packet-like form with a header at its front. Viewed another way, each occupied DTDM frame comprises a transmission overhead field, a header field, and a data field. Thus, the DTDM transmission format is a combination of the circuit transmission format and the packet transmission format.

In the DTDM system, packet and circuit traffic can be multiplexed through the same multiplexer. Thus, such a multiplexer can have continuous circuit type tributaries and bursty packet tributaries. To multiplex

LU 0000934

4,893,306

5

such diverse traffic, a train of DTDM frames with empty payload fields is generated. This train has a bit rate which defines a basic backbone transmission rate for the DTDM transmission system. Data in the form of packets or circuit slots with headers attached are inserted into the empty frames to form the DTDM bit stream.

An appropriate analogy is as follows. The stream of empty DTDM frames may be analogized to a train of empty freight cars. The empty freight cars are then filled with data from the various tributaries which may have been in circuit or packet format.

Illustratively, a DTDM multiplexer may be used to merge traffic from three different communications sources or tributaries into a single DTDM bit stream. These tributaries may be a digital phone generating 64 Kilobits/sec PCM voice, a graphics terminal sending bursty data at 1 Megabit/sec, and a circuit transmission stream operating at the DS3 rate of about 45 Megabits/sec. Illustratively, the bit rate of the backbone DTDM bit stream is 150 Megabits which yields 144,000 frames per second given a 130-byte frame size. The available frames are shared by the three tributaries by giving higher priority to the circuit tributary, and allowing the voice and graphics tributaries to contend on a first-come, first-served basis. The circuit tributary seizes one out of every three empty frames passing by. Thus the regularity of the circuit transmission will be maintained throughout the DTDM transmission link. Illustratively, the voice source is packetized by accumulating up to 15 milliseconds worth of voice samples before inserting this information into an empty DTDM frame along with a header. In this case the voice tributary will on average seize one out of every 2,160 frames. Similarly, at a rate of 1 Megabit per second, the graphics tributary will fill one frame out of 150. In this way, three diverse data streams are multiplexed into a single bit stream.

As a second example, DTDM can be used as a replacement transmission technology to carry existing inter-office traffic. More specifically, consider the need to multiplex and transmit three hierarchical signals at the DS1, DS2, and DS3 rates, respectively, for point-to-point transmission between two offices. The traditional TDM approach would utilize a step-by-step hierarchical approach to multiplex and to subsequently demultiplex these signals. The conventional hierarchical multiplexing scheme requires line conditioning and synchronization circuitry at each level of the hierarchy as well as hardware for bit interleaving.

In contrast, using a DTDM multiplexer, time slots from each of the three signals would be inserted into the empty frames in a basic DTDM backbone signal. If the backbone signal is 150 megabits per second and comprises 144,000 frames per second, the DS3 signal would require one out of every three DTDM frames, the DS2 signal would require approximately one out of every twenty-one DTDM frames and the DS1 signal would require approximately one out of every eighty-four of the empty DTDM frames.

In an actual network, the above-described DTDM streams at the basic backbone bit rate generally contain empty frames; thus DTDM streams may be multiplexed into more densely populated DTDM bit streams at the same bit rate. These more densely populated basic backbone rate bit streams may then be multiplexed into higher bit rate streams for point-to-point inter-office transmission.

6

Details of the assemblers needed to form the basic DTDM bit streams, the disassemblers needed to disassemble the basic DTDM bit streams, and the set of multiplexers and demultiplexers needed to implement DTDM in an actual network are described in detail below along with a framer circuit which plays a significant role in particular implementations of the assemblers/disassemblers and multiplexers/demultiplexers.

BRIEF DESCRIPTION OF THE DRAWING

FIG. 1 schematically illustrates the DTDM transmission format, in accordance with an illustrative embodiment of the invention;

FIG. 2 schematically illustrates the formation of a backbone DTDM, bit stream, in accordance with an illustrative embodiment of the invention;

FIG. 11 illustrates a demultiplexer for use in connection with point-to-point transmission; and

FIG. 12 illustrates a framer circuit.

DETAILED DESCRIPTION

1. DTDM Transmission Format

DTDM is an approach to data transport which can handle both TDM hierarchical signals and packet traffic in a common integrated structure, while allowing complete bit rate flexibility. As illustrated in FIG. 1, the transmission bit stream is divided into frames 1. The DTDM frame is the fundamental unit of information transport in the DTDM transmission scheme. The frames come one after the other so as to form a continuous chain or train.

Each frame 1 comprises two fixed length fields designated transmission overhead (T) and payload in FIG. 1. Illustratively, each frame comprises 130 bytes with 10 bytes being allocated to the transmission overhead field.

Typically, the bit rate of the DTDM bit stream illustrated in FIG. 1 is about 150 Megabits/sec. The following information may be available in the overhead field of every DTDM frame; frame alignment word for frame timing, empty/full status of the frame, and span identification.

As shown in FIG. 1, the payload field of each frame may be filled with a data packet including a header (H) or a slot from a circuit transmission stream. However,

LU 0000935

4,893,306

7

before a slot from a circuit transmission stream can be inserted into the payload field of a DTDM frame, it must first be converted to packet-like form by the insertion of a header (H) at its front. Viewed another way, each occupied DTDM frame comprises a transmission overhead field, a header field, and an information field. Thus, the DTDM transmission format is a combination of the circuit transmission format and the packet transmission format. The packet header provides information such as channel number, line number, error detection, etc. In general, only the information required in every frame gets permanent bandwidth allocation in the transmission overhead field.

FIG. 2 schematically illustrates the formation of a DTDM bit stream. The DTDM bit stream assembler 3 can combine into a single bit stream both continuous circuit tributaries and bursty packet tributaries. Three such tributaries are illustrated in FIG. 2. They are: a digital phone tributary 5 generating 64 Kilobits/sec PCM voice, a tributary 7 from a graphics terminal sending bursty data at one megabit per second, and a circuit transmission stream 9 operating at the DS3 rate of about 45 Megabits/sec. Each of the three tributaries has a characteristic shading in FIG. 2 so that it is possible to follow how data from the three tributaries is combined to form the DTDM bit stream.

To multiplex such diverse traffic, a train 10 of DTDM frames with empty payload fields is generated. This train 10 has a bit rate which defines a basic backbone transmission rate for the DTDM system. Each of the frames in the train 10 has an occupied transmission overhead field (T).

Illustratively, the train of frames has a bit rate of about 150 Megabits per second and comprises 144K blocks/sec. The assembler 10 serves to insert data from the tributaries 5, 7, 9 into the payload fields of the DTDM frames in the stream 10. To accomplish this, the tributaries 5, 7, 9 are first packetized using packetizers 11, 13, 15, respectively to form the packetized streams 17, 19, 21. Each packet comprises a header (H) and an information field. In the case of the tributary 5, up to 15 milliseconds of speech samples are accumulated to form a packet. In the case of the circuit tributary each slot is converted to packet form by placing a header at the front thereof.

To form the DTDM stream 10, the packets comprising the streams 17, 19, 21 are inserted into the empty payload fields of the empty frames in the stream 10. The empty frames are shared by the three tributaries by giving higher priority to the circuit tributary 9 and allowing the voice and graphics tributaries 5, 7, to contend for empty frames on a first-come, first-served basis. Thus, the circuit tributary seizes one out of every three frames so that the regularity of the circuit transmission is maintained throughout the DTDM transmission link. Similarly, the voice tributary will seize one out of every 2,160 frames and the graphics tributary will seize on average one out of every 150 frames. It should be noted that the bit stream 12 is not 100% occupied and that some frames remain empty. In this way, three diverse tributaries are multiplexed into a single DTDM bit stream.

2. A Network Utilizing DTDM

FIG. 3 schematically illustrates an end-to-end network 20 utilizing DTDM. The network 20 connects to customer premises equipment (CPE) 22, of which three types are illustrated, namely video, voice and data.

8

In the network 20, three multiplexing stages are required to support end-to-end transport. In the user-network interface stage 30, an assembler 32 receives data streams on lines 21 from the customer premises equipment 22 and combines these streams into a basic backbone DTDM stream of the type discussed in connection with FIGS. 1 and 2. Similarly, disassembler 34 tears apart a basic DTDM bit stream arriving on line 33 and distributes the data to the appropriate customer premises equipment 22 via lines 23.

As indicated above, the DTDM bit stream formed by the assembler 32 is not 100% occupied. Thus the multiplexer 36 in the remote electronics stage 38 is used to combine several DTDM bit streams arriving on lines 62 into a more densely occupied DTDM bit stream of the same bit rate to achieve greater transmission efficiency. Similarly, the demultiplexer 39 separates a densely populated DTDM bit stream arriving on line 120 into less densely populated DTDM bit streams transmitted via lines 33, so that the data contained therein can ultimately be routed to the correct customer premises equipment.

In the point-to-point stage 40, a plurality of DTDM bit streams arriving via lines 63, 150 are time division multiplexed by means of time division multiplexer 42 for high speed point-to-point transmission via line 165 to a network switch (not shown). For example, the multiplexer 42 receives one DTDM stream via a line 63 from multiplexer 36 and another DTDM stream via line 150. The DTDM bit stream transmitted via line 150 is formed by DTDM assembler 43 and contains the data of three DS3 tributaries 45.

Time division demultiplexer 44 receives a high speed bit stream from a switch (not shown) via line 170 and demultiplexes this stream into a plurality of DTDM streams. One DTDM stream containing data for customer premises equipment goes to demultiplexer 39 via line 120 and another DTDM stream comprising DS3 slots goes to disassembler 47 via line 179.

3. DTDM Assembler and Disassembler

The function of the DTDM bit stream assembler 32 of FIG. 3 is to packetize each incoming data stream associated with one particular customer service or transmission channel and then embed these packets into the basic DTDM transmission frames. The assembler 32 is shown in greater detail in FIG. 4.

The assembler 32 comprises a plurality of interface units 50. Each interface unit 50 serves to interface an associated data input 21 with the DTDM bit stream. A DTDM bit stream comprising empty frames with empty payload fields is generated by framer unit 52. A detailed description of the framer unit is provided below.

Each interface unit includes a framer unit 53. The framer units 52, 53 are connected together in a daisy chain fashion. The frames comprising the DTDM bit stream are passed along the daisy chain from one framer unit to the next. More particularly, the DTDM bit stream leaves the serial data output (sdo) of the framer unit 52 and enters the serial data input (sdi) of the topmost framer unit 53. The DTDM bit stream leaves the topmost framer 53 via its serial data output (sdo). The DTDM bit stream then enters the serial data input (sdi) of each succeeding framer unit and leaves via the serial data output (sdo) of each framer unit. The DTDM bit stream leaves the serial data output of the lowermost framer via line 62. As shown in FIG. 3, line 62 serves to

LU 0000936

4,893,306

9

transmit the DTDM bit stream to the DTDM multiplexer 36. If the DTDM frame currently located at the framer unit 53 of a particular interface 50 is empty, that interface may insert a packet into the payload field of the DTDM frame.

The data inputs 21 to the assembler 32 are connected to the customer premises equipment 22 of FIG. 3 and may have a wide range of bit rates; for example, the data inputs 21 can be video, voice, data, or different digital hierarchical transmission signals (DS-1, DS-2 and DS-3). Therefore, the assembler architecture must be capable of efficiently accommodating different input bit rates and be flexible enough to allow for future expansion or for the changing of particular input connections to different services. The architecture shown in FIG. 3 provides the capability to easily add or drop a particular input service.

Each input 21 is connected to a packetizer 55 which forms part of the associated interface unit 50. The packetizer 55 puts the incoming data into a packet structure by adding a packet header at the beginning of appropriate segments of the input bit stream. The packet header carries information about the packet, such as packet occupancy, channel identification number, line identification number, check sum and so on. Illustratively, the channel identification number is used to identify the input service from which the packet originated. After the data is put into a packet structure, it is stored in a FIFO 57 with byte wide format. The framer unit 53 then reads the data from the FIFO 57 into its parallel data input (pdi) 58 and generates properly framed data bits which are inserted into an empty payload field of a DTDM frame currently at the particular framer unit 53.

However, a framer unit 53 will not read the data from the FIFO 57 unless two conditions are met. One is that the "packet-ready" pulse signal from the packetizer 55 is asserted, indicating one packet is completely stored in the FIFO. The other condition is that the incoming DTDM frame on the serial data input (sdi) of the framer 53 is not already occupied by a valid packet, i.e. the incoming DTDM frame is empty. Thus, an empty or "emp" signal is transmitted from the framer 53. The "packet-ready" signal triggers an enable signal, "en", in the framer unit to be asserted for the whole frame transmission period allowing the data packet to be moved from the FIFO 57 through the framer 53 and into the DTDM bit stream. Using the "emp" and "en" signals, control logic 59 controls the reading of a packet out of the FIFO 57 and into the framer 53.

Since the framer units 53 are daisy-chained together, the contention for empty DTDM frames is automatically resolved in favor of input services having positions closer to the empty frame generator.

In order to simplify the assembler 32 of FIGS. 3 and 4 and hence reduce the building cost, one practical assumption may be utilized; the total traffic of all inputs at any given time is less than the bit rate of the basic backbone DTDM stream.

The topmost framer 52 in FIG. 4 does not have any input service connected to it. It generates the chain of empty DTDM frames which are sent to the following framers 53. If none of the interfaces 50 insert a packet into a particular frame, an empty frame is finally sent out through the serial data output (sdo) of the bottommost framer unit on lead 62.

After the DTDM bit stream has traveled through the entire communications network 20 of FIG. 3, which network includes multiplexers, switches, and demulti-

10

plexers, etc., the DTDM bit stream is disassembled and the data distributed to the appropriate customer services equipment. In the network 20 of FIG. 3, the disassembler 34 is used for this purpose. The disassembler 34 is shown in greater detail in FIG. 5. Illustratively, the disassembler 34 removes both the transmission overhead and packet header field from each incoming DTDM frame and distributes the data contained in the frame to the desired customer premises device.

More particularly, the assembler 34 comprises a plurality of interfaces 66. Each interface 66 receives the incoming DTDM bit stream via line 33 (see FIG. 3) and is illustratively connected to one customer premises device via an output lines 23 (see FIG. 3). Each incoming DTDM frame is simultaneously received by the framer unit 70 in each interface 66. However, only packets containing data to be transmitted to the associated customer premises equipment are transferred from the framer 70 to the associated FIFO 72. To accomplish this, the packet occupancy and channel identification number are examined by the framer 70. The framer 70 in turn generates proper control signals via lines 73, which, along with control logic 74, determine whether or not the packet carried in the payload field of the particular DTDM frame will be written into the FIFO 72 of the particular interface unit so that the data contained in the packet can be transmitted to the associated customer premises equipment.

Recovering the correct frequency from the incoming data is a very challenging task. Although for each kind of customer premises equipment or service the frequency is known, the difference between the local reading clock used to read data out of the FIFO 72 and the clock which was used to load data into empty frames at the transmit end may result in overflow or underflow of the FIFO 72. Illustratively, a phase locked loop 78 is used to modify the local reading clock in order to cancel this difference in clock rates.

As shown in FIG. 5, the local reading clock signal (line 73a) used to read data out of the FIFO 72 is phase locked with the incoming data so that the data can be read out correctly from the FIFO 72 without overreading or underreading. The rate at which data is read out of the FIFO is determined by the frequency of the voltage controlled oscillator 76 in the phase locked loop 78.

The packet is written into the FIFO 72 with the network clock rate, but read out at a rate dependent on the particular equipment to which the data is transmitted. An "hf" signal which indicates that the FIFO 72 is half full is smoothed out by a low-pass filter 75 whose output is used to control the output frequency of a voltage-controlled oscillator 76. If information is read out of the FIFO 72 faster than information is written into the FIFO 72, then the "hf" signal will not be asserted. This causes the voltage output from the low-pass filter 75 to decrease, reducing the output frequency produced by the voltage controlled oscillator and reducing the rate at which data is read out of the FIFO 72. Similarly, if information is read out of the FIFO more slowly than it is being written into the FIFO 72, the "hf" signal will be asserted and the voltage controlled oscillator frequency will be increased so that the read clock signal frequency is larger. The same interface unit 66 can be used for different customer premises devices by choosing a proper frequency for oscillator 69.

Data packets read out of FIFO units 72 are depacketized by means of depacketizer circuits 79 which serve to remove the headers. The resulting data is then trans-

LU 0000937

11

mitted via lines 23 to the appropriate customer premises equipment.

4. DTDM Bit stream Multiplexer and Demultiplexer

The function of the DTDM bit stream multiplexer 36 of FIG. 3 is to concentrate a plurality of relatively sparsely occupied incoming DTDM streams into at least one more densely occupied DTDM stream of the same bit rate, resulting in more efficient use of the transmission facility. There is more than one architecture for implementing the DTDM multiplexer 36 of FIG. 3.

One embodiment of such a DTDM bit stream multiplexer is illustrated in FIG. 6. The DTDM multiplexer 36 of FIG. 6 comprises N input lines 62 (see FIG. 3) and one output line 63 (see FIG. 3). Line buffers 64 recognize and queue incoming DTDM frames. The server 65 looks for newly arrived DTDM frames in the line buffers 64, adds a proper line number in the header field, and sends the frames out in a more densely occupied DTDM bit stream.

The primary functions of the line buffers 64 are recognition and queuing of incoming DTDM frames. Each line buffer contains a serial/parallel converter 66 for converting incoming serial DTDM frames into parallel form and a first-in, first-out buffer 67 with capacity for multiple frames. A timing and control circuit 68 operates the line buffer and interfaces it with the server.

The main functions of the server 65 are to look for newly arrived DTDM frames in the line buffers, to modify the header field to include a line number, and to place the DTDM frame in a more densely occupied DTDM bit stream. The server comprises a header insert circuit 69 for modifying the header field of the DTDM frames, a controller circuit 70 for interfacing with the line buffers 64, and a parallel to serial converter 70. The operations of the server are pipelined; while the server reads a DTDM frame from a line buffer and places it in an outgoing DTDM stream, it continues searching line buffers for DTDM frames. It should be noted that the multiplexer of FIG. 6 is useful for multiplexing packets in non-DTDM transmission formats in addition to being useful for DTDM bit streams.

Another possible architecture for a multiplexer capable of combining several relatively sparsely occupied DTDM bit streams into a more densely occupied DTDM bit stream of the same bit rate builds on the architecture of the DTDM bit stream assembler 32 of FIG. 4. Each input to an interface unit 50 of FIG. 4 is replaced by a serial data link on which a DTDM bit stream arrives. The data packets contained in the frames comprising the incoming DTDM bit stream contend for output frames in an outgoing DTDM bit stream. The frames comprising the outgoing DTDM bit streams are generated by the framer 52 and passed along the chain of interconnected framers 53. The interface units 50 insert data packets from incoming DTDM frames into the frames of the outgoing bit stream to form a more densely occupied DTDM bit stream. The contention for output frames is resolved automatically by the daisy-chained connection of the framer units. Note that no packetizer is needed in the interface units, and the length of each FIFO is preferably more than two frames to prevent data packets contained in incoming frames from being lost.

FIG. 7 schematically illustrates an alternative DTDM bit stream multiplexer for combining a plurality of relatively sparsely occupied DTDM bit streams into a smaller number of more densely populated DTDM bit

4,893,306

12

streams of the same bit rate. The multiplexer 36' of FIG. 7 has the flexibility to receive N input DTDM bit streams and to transmit M output DTDM bit streams, which allows M output lines to be shared by N input lines. It is known that both the probability of buffer overflow and the average delay for bursty traffic can be significantly decreased by increasing the number of outputs.

Using the multiplexer architecture 36 shown in FIG. 6, it is difficult to build an N:M multiplexer, because the service order is determined by a single central server. However, it is possible to provide a multiplexer system comprising M separate multiplexers of the type shown in FIG. 6, each having N/M input lines and line buffers and one server and associated output line. In contrast, the service order in the multiplexer 36' of FIG. 7 is determined locally, which results in the flexibility of reassigning input lines to different output lines based on the input traffic statistics.

The N:M multiplexer 36' of FIG. 7 comprises a plurality of input lines 62 (see FIG. 3) and a smaller number of output lines 63 (see FIG. 3). DTDM frames arriving on the input lines 62 are converted into a byte wide stream by means of the serial-to-parallel converters 86 and stored in the associated buffers (FIFOs) 88. The operation of the framer units 90, 92 is similar to those in the DTDM bit stream assembler of FIG. 3. Each framer 90, 92 has a parallel data input (pdi), a serial data input (sdi) and a serial data output (sdo). Framer 90, the head-end framer unit, doesn't have any input lines connected to it. In normal operation, it continuously sends out a chain of empty frames. The remaining framers 92 take data comprising occupied DTDM frames in the buffers 88, and insert this data into the empty frames generated by the framer 90, so as to combine a plurality of sparsely occupied DTDM bit streams into a smaller number of more densely populated DTDM bit streams.

The N:M multiplexer 36' of FIG. 7 comprises an $(N+M) \times (N+M)$ broadcasting cross point switch network 95. The serial data output (sdo) of each framer 90, 92 is connected to an input of the switch, and the serial data input (sdi) of each framer 9 is connected to an output of the switch as shown in FIG. 7. The connections through the switch network are controlled by a dedicated controller 97.

Illustratively, when the system is initialized, the N input lines 62 are divided into M groups, $(1, 2, \dots, J), (J+1, J+2, \dots, 2J), \dots, (MJ+1, \dots, (M+1)J)$, where $J = N \bmod M$. The J input lines in each group are logically connected as shown in FIG. 8. Each group of input lines is associated with one output line. Thus, all of the DTDM frames arriving at the inputs of one group are merged into a single DTDM bit stream which leaves via the associated output. The topmost framer unit 92 in each group receives empty frames broadcast from the framer 90. Each frame is then passed through the switch 95 from one framer in the group to the next framer in the group. If a particular FIFO 88 has data comprising a DTDM frame and the associated framer 92 receives an empty frame, the data is inserted into the empty frame. Thus, within each group service priority is ranked in descending order with the higher priorities near the top. Ultimately, M relatively densely occupied DTDM bit streams leave the multiplexer of FIG. 6 via the outputs 63.

Thus, with the addition of the cross point switch, more than one framer 92 receives empty frames from the framer 90 at the same time. This achieves the N:M

LU 0000938

4,893,306

13

multiplexing function automatically and with minimal complexity.

If the input lines are not grouped so as to distribute output traffic evenly, the input lines can be regrouped easily by changing the connections within the switching network 95. For example, a particular input in the first group of inputs may be assigned to any other group, e.g., the second group of inputs, to spread out traffic evenly. The controller 97 must know the traffic statistics of each input line and follow some algorithm to rearrange the inputs and decide the ordering (priority) within each group.

The DTDM multiplexer of FIG. 7 may route DTDM frames arriving on the same input line to different output lines. For example, n frames arriving on an input line have been sent to output #1. But the $(n+1)$ th frame may be switched to output #2 because reconfiguration took place to balance traffic among the output lines. This may cause an out of sequence problem if the $(n+1)$ th frame arrives at the receive end before the n th frame does. The cost to reorder the frame sequence at the output end may be high. Illustratively, to avoid this problem, one rule may be followed: the input lines carrying services with high bit rate information, such as video, will not be switched from one input line group to another during the service period. For a low bit rate service, such as voice at 64 Kb/s, even if two consecutive frames containing data are dispatched onto two different output lines, the two frames from such a bursty service will be separated by more than several hundred frame intervals. Hence, it is unlikely for there to be an out of sequence problem in this case.

It should be noted that multiplexer architecture of FIG. 7 may be used to multiplex other types of traffic besides DTDM traffic. For example, streams of data packets may be multiplexed together to form more densely occupied streams.

Turning now to FIG. 9, the DTDM bit stream demultiplexer 39 of FIG. 3 is illustrated in greater detail. The function of the DTDM bit stream demultiplexer 39 is to separate a relatively densely occupied incoming DTDM bit stream into a plurality of relatively sparsely occupied outgoing DTDM bit streams of the same bit rate so that the user data in the frames can ultimately be transported to the proper customer premises devices.

The demultiplexer 39 of FIG. 9 has one input line 120 (see FIG. 3) and a plurality of output lines 33 (see FIG. 3). Each output line 33 is connected to the input line 120 by means of an associated interface 124. Any incoming DTDM frame is simultaneously received by the framer unit 126 in each interface 124. The frame occupancy and line identification number of each incoming DTDM frame are examined by the framers 126. If the frame is not empty and the line number is matched, the packet contained therein will be written into the FIFO 130 under the control of logic 128 and then read out of the FIFO 130 by the framer 132 at the output end of the interface 124 under the control of logic 134. Otherwise, the packet is simply discarded. In this manner, the data from each incoming frame is routed to the correct output line. A counter 136 in each interface is used to count the number of bytes written into the FIFO 130 and generates a signal when a full packet is stored in the FIFO. This signal will inform the output framer 132 to start reading the packet in the FIFO. The framer 132 will assert the "en" signal during the reading of the entire packet. The framers 132 generate sequences of DTDM frames. These sequences of

14

frames leave the framer 132 via the serial data outputs and form the outgoing DTDM bit streams on the lines 33. When data packets are present in the FIFOs 130 they are inserted into the frames generated by the framers 132. In particular embodiments of the demultiplexer, the functions of the framer units 126, 132 may be performed by a single framer unit.

5. Time Division MUX/DEMUX for DTDM Bit Stream

After relatively sparse DTDM bit streams are concentrated into more densely populated DTDM bit streams of the same bit rate using for example, the DTDM multiplexer 36 of FIG. 3, a plurality of such more densely populated bit streams may be time division multiplexed into a higher speed data stream using, for example, the time division multiplexer 42 of FIG. 3. Such high speed data channels may be used for communications to and from central offices.

Usually, the most challenging work in a time division multiplexing system is to synchronize all incoming bit streams so that they have a common bit rate before they are interleaved into a higher bit rate stream. Typically, the input bit streams have the same nominal center frequency but drift independently a small amount from the center frequency. The conventional way to overcome the asynchronization among the input bit streams is positive bit or byte stuffing. The frequency of the high speed output bit stream is made greater than the product of the nominal center frequency and the number of input tributaries. There is usually a bit or byte position reserved for the occasional stuffing of a dummy bit or byte. Also, there is some control overhead used to indicate if the bit or byte at the stuffing position is valid.

By taking advantage of the fact that the frames comprising each input DTDM bit streams are not 100% occupied, the frequency of the higher speed output bit stream can be made exactly equal to the nominal center frequency of the input tributaries times the number of the input tributaries. In the case of a DTDM system, this can be accomplished through the positive and negative stuffing of DTDM frames. Since the frequency of each input tributary signal can be adjusted in the positive or negative direction through the insertion or removal of an empty DTDM frame, it is possible to make the frequency of the high-speed multiplexed bit stream exactly an integer multiple of the nominal input tributary frequency.

A time division multiplexer 42 (see FIG. 3) for multiplexing a plurality of DTDM bit streams is illustrated in FIG. 10. Each input 63, 150 (see FIG. 3) is connected to an interface unit 152. Each interface unit 152 comprises a framer 154 which is clocked by a clock signal derived from a clock recovery circuit 156. The derived clock, which is the actual frequency of the tributary, may differ slightly from the nominal tributary frequency as discussed above. This difference between the nominal and actual frequencies is eliminated in the interface unit. Each incoming DTDM frame will be examined by the framer 154 in the associated interface 152 for its occupancy. The data packets contained in the occupied frames will be written into the FIFO 158 under the control of logic 159 and read out later by the framer 160 at the output end of the interface unit 152. Empty frames are discarded.

The reading of the data packets from the FIFOs 158 to the parallel data inputs (pdi's) of the framers 160 is synchronized. The serial data input (sdi) of each framer

LU 0000939

4,893,306

15

160 is connected to the serial data output of a framer 162. The framer 162 serves to broadcast empty frames to the framers 160 so that each framer 160 receives a synchronous chain of empty frames at the nominal tributary frequency. The empty frames received by each framer unit 160 are filled with data packets from the associated FIFO 158 to produce synchronized tributary bit streams at the nominal tributary frequency.

If the actual frequency of a particular tributary is less than the nominal center frequency then on occasion, the associated FIFO 158 will not have a packet to insert into an empty DTDM FRAME. The net effect is that an empty DTDM frame is added so that the tributary acquires a frequency equal to the nominal frequency. However, if the actual frequency of the tributary is larger than the nominal center frequency the net effect is that empty DTDM frames are dropped so that the tributary acquires a frequency equal to the nominal frequency. Illustratively, the difference between the actual and nominal tributary frequencies is on the order of ten parts per million. In this case, a two frame capacity FIFO 158 is sufficient as long as each input tributary has one empty frame in 10^5 .

All of the framers 160 send out frames at the same time, with frame alignment being automatically achieved. The aligned frames are then bit interleaved using bit interleaving circuit 164 to produce a single high bit rate bit stream at output 165 (see FIG. 3). Note that the clocks of the framers 160 are connected together so that data bits coming from the framers 160 are phase aligned and can be bit interleaved directly. The clock for the framers 160 is provided by the clock generator 166 and frequency divider 167. In an alternative embodiment of a time division multiplexer, instead of bit interleaving, frame or byte interleaving may also be used. If the frame interleaving is used then the multiplexed output bit stream has the same DTDM frame structure, thereby allowing the flexible single transport architecture to grow as the technology advances.

A time division demultiplexer 44 (see FIG. 3) for demultiplexing the high speed bit stream is illustrated in FIG. 11. The high speed data stream arrives on input line 170 (see FIG. 3) and is bit deinterleaved by means of bit deinterleave circuitry 172 into several lower speed tributary bit streams which are transmitted outward on lines 174. In order to dispatch the bits to correct tributaries, a predetermined span identification (SP ID) is inserted for each tributary before they are multiplexed at the transmit side. The tributary present on line 174a is connected to a framer unit 176, which will detect the frame boundary and determine by examining the span identification whether or not the bit deinterleave circuitry has correctly aligned the incoming bit stream so that appropriate data goes to appropriate output tributaries. If not, either a skip pulse is generated to rotate the bit sequence or a signal is generated by the framer 176 and sent to a cross point switch 178 to reassign the order of the bit stream. The bit streams with correct bit assignments appear at outputs 120, 179 (see FIG. 3). Alternatively, instead of the crosspoint switch 178, a barrel shifter may be used. It should be noted that the clock for the bit deinterleave circuit 171 and framer 176 is provided by clock recovery circuit 180 and frequency divider 182. Demultiplexers which operate according to similar principles are disclosed in R. J. Boehm et al. "Standardized Fiber Optic Transmission Systems - A Synchronous Optical Network View" IEEE Journal on Selected Areas in Communications

16

VOL SAC-4 No. 9 pp 1424-1431 Dec. 1986 and L. R. Linnell "A Wide-band Local Access System using Emerging-technology Components" IEEE Journal on Selected Areas in Communications" VOL SAC-4 No. 4 pp 612-618 July 1986.

6. The Framer Circuit

The framer unit is an important component for the implementation of specific embodiments of the assemblers, disassemblers, multiplexers and demultiplexers which comprise the DTDM network discussed above.

The framer unit performs a number of functions in the DTDM network, including generating trains of empty DTDM frames, enabling the writing of data packets into specific DTDM frames, and the examination of header data in specific DTDM frames to generate signals for the control of peripheral circuits (e.g. in a DTDM demultiplexer to determine if data in a particular DTDM frame belongs to particular customer premises equipment or a particular less densely occupied DTDM bit stream). All of these functions may be carried out by the framer unit discussed below.

A framer unit 200 is schematically illustrated in FIG. 12. Illustratively, the framer unit 200 is formed as a single chip. The framer unit 200 has a serial data input 202, a parallel data input 204, a serial data output 206 and a parallel data output 208. Timing information for the framer unit 200 is provided by timing generator 209. The framer 200 operates under control of a control unit 210 which illustratively comprises one or more finite state machines.

As indicated above, a plurality of framer units may be connected in a daisy chain fashion and DTDM frames may be passed from one framer to the next (see e.g., framers 53 of FIG. 4). Data may be written into an empty DTDM frame as follows. A DTDM frame is received at the serial input 202. The DTDM frame is converted to parallel form by serial-to-parallel converter 212 and is detected by frame detector 214. The frame detector 214 is in communication with the control 210 and illustratively communicates to the control 210 information such as whether or not the frame is empty. Illustratively, the DTDM frame leaves the framer unit via the serial output 206 after conversion to serial form by way of parallel-to-serial converter 216. However the frame cannot reach the parallel-to-serial converter 216 unless the control 210 applies a signal to the tristate device 218.

The data to be written into the frame is received at the parallel data input 204 (illustratively from a FIFO 57 in the DTDM bit stream assembler 32 of FIG. 4). If the particular DTDM frame is empty and data is available at the parallel input 204, a signal is applied by the control 210 to the tristate device 220 to enable the data to be inserted into the particular DTDM frame via bus 219 before it leaves the framer unit. However, if the DTDM frame is already full the control does not provide such a signal to the tristate 220. In particular framer units additional information such as span identification may be inserted into specific DTDM frames by means of an additional tristate unit not shown.

The framer unit 200 may also be utilized to generate a chain of empty DTDM packets (see e.g., framer 52 in FIG. 4). In this case the serial input 202 and associated serial-to-parallel converter 212 are not utilized. Instead, the control 210 applies a periodic signal to tristate 222 so that a frame alignment word is periodically read from frame byte ROM 224 and transmitted via bus 219 to

LU 0000940

4,893,306

17

parallel-to-serial converter 216 and serial output 206 so as to define a train of empty DTDM frames. Other information comprising the transmission overhead (T) field of the DTDM frame may also be stored in ROM 224 or provided by other sources connected to the bus 219 via a tristate device operative under the control of the control unit 219.

In particular situations (see e.g., framers 70 of FIG. 5 and 126 of FIG. 9), a framer unit receives occupied DTDM frames and the header (H) or transmission overhead (T) fields have to be examined to control peripheral circuit operations such as the reading of data into a FIFO. In this case, a multiple byte delay unit 230 may be included in the path between the serial input 202 and the parallel and serial outputs 208, 206. Typically a frame arrives at the serial input 202 and is converted to parallel form by the serial-to-parallel converter 212. The frame detector detects the frame and supplies necessary information from the header or transmission overhead fields to the control unit 210 which issues appropriate control signals via lines 232 such as user read/write strobes. Illustratively, the user read/write strobes control the writing of data from DTDM frames in the framer unit into associated FIFOs or other buffers. If the FIFO has byte wide format, the parallel output 206 may be used for this purpose. The delay unit 230 is used to insure that the necessary signal processing takes place before the DTDM frame leaves the framer unit.

7. Conclusion

A data transmission technique known as Dynamic Time Division Multiplexing (DTDM) has been disclosed along with an end-to-end network utilizing DTDM.

Finally, the above described embodiments of the invention are intended to be illustrative only. Numerous alternative embodiments may be devised by those skilled in the art without departing from the spirit and scope of the following claims.

What is claimed is:

1. A method for simultaneously transmitting data from sources having different bit rates in a telecommunication network comprising the steps of:

generating a bit stream comprising a sequence of frames, each of said frames including a transmission overhead field containing frame timing information and an empty payload field, and

filling the empty payload fields in said frames with data in packetized format from a plurality of sources which have access to the bit stream including circuit or packet sources, such that data in packetized format from any of said sources is written into any available empty payload field of any of said frames for transmitting data from each of said sources at its own desired bit rate via said bit stream and for transmitting data from said plurality of sources simultaneously via said bit stream.

2. The method of claim 1 wherein prior to filling said frames with slots from a circuit transmission stream, said slots are converted to said packetized format by placing a header in front of each of said slots.

18

3. A method for generating a bit stream capable of transporting data originating from both circuit transmission and packet sources comprising

generating a bit stream comprising a sequence of frames, each of said frames including a transmission overhead field containing frame timing information and an empty payload field,

packetizing data from a plurality of sources having different bit rates and which have access to said bit stream including circuit transmission sources or customer premises equipment to produce data packets, and

inserting said packets from said sources into the empty payload fields of said frames such that a packet from any of said sources is inserted into any available empty payload field of any of said frames for transmitting data from each of said sources at its own desired bit rate via said bit stream and for transmitting data from said plurality of sources simultaneously using said bit stream.

4. An apparatus for assembling a dynamic time division multiplexing bit stream comprising,

generating means for generating a train of frames wherein each frame includes a transmission overhead field containing timing information and an empty payload field,

processing means for processing data from a plurality of sources into packet format, and

inserting means for receiving said train of frames and for inserting each of said packets comprised of data from one of said plurality of sources into any empty payload field of any of said frames available to said inserting means to form said bit stream so that data from each of said sources can be transmitted at its own desired bit rate via said bit stream and so that data from said plurality of sources can be transmitted simultaneously via said bit stream.

5. The apparatus of claim 4 wherein said sources include circuit transmission bit streams or customer premises equipment.

6. An apparatus for assembling a bit stream for transmitting data from a plurality of sources comprising:

means for generating a train of frames, each of said frames including a transmission overhead field and an empty payload field, and

a plurality of interfaces, each of said interfaces serving to interface one of said sources with said train of frames, each of said interfaces comprising:

packetizing means for converting data into data packets,

memory means for storing at least one of said packets formed by said packetizing means, and

circuit means for inserting a packet stored in said memory means into any empty payload field of any available one of said frames so that data from each one of said sources can be transmitted at its own desired bit rate via said bit stream and so that data from said plurality of sources can be transmitted simultaneously via said bit stream.

7. The apparatus of claim 6 wherein said interface units are connected to one another serially and wherein said frames are passed sequentially to each of said interface units to receive said packets in said empty payload fields.

2. Telcordia objects to each definition, instruction, and interrogatory to the extent it would require Telcordia to respond beyond that required by the Federal Rules of Civil Procedure or this Court's Local Rules.
3. Telcordia objects to Lucent's interrogatories to the extent they seek third-party information in Telcordia's possession, custody, or control that is subject to agreement, court order, or other duty preventing disclosure to Lucent. Telcordia objects to responding to propounded interrogatories that require the disclosure of trade secrets or other proprietary and confidential information of third parties unless Telcordia receives permission to disclose such information from such third parties or is otherwise compelled to produce the information by court order.

*Contains Telcordia, Lucent, and PMC-Sierra Confidential Information
Subject to Protective Order*

RESPONSES TO INTERROGATORIES

INTERROGATORY NO. 1:

With respect to each claim of the '306 Patent that you contend Lucent "has infringed ... by making, using, offering for sale, selling, and/or importing into the United States communication network products embodying the patented invention," *Telcordia Complaint at ¶ 12*, and/or that you contend Lucent "has infringed ... by inducing others to infringe and/or contributing to the patent's infringement by others," *id. at ¶ 13*, identify each product that you contend infringes and describe with full particularity all factual and legal bases for your contention, including a construction of each element of the asserted claims with all intrinsic and extrinsic evidence relating to the construction, a description of how each element of each asserted claim is found in each accused product, whether such element is found in the accused product literally or by equivalence, and whether such infringement is direct or indirect.

SUPPLEMENTAL RESPONSE:¹

Telcordia incorporates by reference each of the applicable general objections as though fully set forth herein. Telcordia objects to this interrogatory as unduly burdensome to the extent it prematurely seeks the disclosure of information, such as claim charts and claim constructions, at this early stage of discovery and prior to a time set for disclosure of such information by a court scheduling order or by a schedule set by the mutual agreement of the parties. Telcordia objects to this interrogatory as premature to the extent discovery of Lucent's documents, materials, and information is needed to respond. Telcordia objects to this interrogatory to the extent it seeks information that is protected by the attorney-client privilege or by the attorney work product immunity. Because it consists of multiple parts and sub-parts, Interrogatory No. 1 is improperly listed as a single interrogatory.

Pursuant to an agreement between the parties, the discovery requests of both Lucent and Telcordia that are directed to the '306 patent, or to the "Patents-In-Suit," shall be interpreted to cover not only the '306 patent, but also the '633 and '763 patents. Telcordia's supplementation

¹ Due to time constraints, Telcordia has not eliminated from its response products which have been removed from the case.

of this interrogatory with information regarding the '633 and '763 patents incorporates and is subject to all of the General and Specific Objections already asserted as to this interrogatory.

Subject to and without waiving any of these general and specific objections and reserving its right to supplement its response as discovery proceeds, Telcordia responds to this interrogatory as follows:

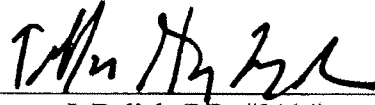

'306 Patent

Based upon information that is currently available to Telcordia, Lucent's infringing products include products that map packetized data into SONET frames, such as any Lucent products having components with framing chips that map packets (e.g., ATM cells or other packets) into SONET frames. These products include any Lucent product or process using "S/UNI" framing chips for mapping packets (ATM cells) into SONET frames, including Lucent's CBX-500 Multiservice WAN switch equipped with ATM enabled ports. Other infringing Lucent products include the CBX 500 switch using physical layer devices other than S/UNI ATM framing chips, the DMX Access Multiplexer, the GX-550 Multiservice WAN Switch, the PacketStar PSAX 1000, 1250, 2300, and 4500 platforms, CBX-3500 Multiservice Edge Switch, DMXtend Access Multiplexer, DMXplore Access Multiplexer, DMXpress Access Multiplexer, DDM 2000, LambdaUnite Multiservice Switch, Flexent Serving GPRS Support Node (SGSN), Lucent Gateway GPRS Support Node (GGSN), AnyMedia Access System, AXC 2000, APX 1000, APX 8000, MAX TNT Universal Gateway, APX 8100, Stinger series of products (including Stinger FS+, Stinger RT, Stinger LS, Stinger DSL, and Stinger MRT), 5E-XC Switch, Lucent Compact Switch, PacketStar AC 60, PacketStar PSAX 20, B-STDX 8000/9000, and TMX-880. Such Lucent products literally infringe at least one or more of

claims 1, 3, and 4 of the '306 patent as shown in the following charts, subject to updating as discovery proceeds and as claim language is construed by the Court:

<u>Claim 1, '306 Patent</u>	<u>Lucent Products with ATM SONET Framing Chips*</u>
1. A method for simultaneously transmitting data from sources having different bit rates in a telecommunication network comprising the steps of:	An ATM output port of the Lucent product transmits ATM cells containing data from sources having different bit rates.
generating a bit stream comprising a sequence of frames, each of said frames including a transmission overhead field containing frame timing information and an empty payload field, and	The ATM SONET framing chips in the Lucent products generate a bit stream comprising a sequence of SONET frames, each frame including a transmission overhead field including A1, A2 frame timing bytes and an empty payload field containing "idle cell" bytes.
filling the empty payload fields in said frames with data in packetized format from a plurality of sources which have access to the bit stream including circuit or packet sources, such that data in packetized format from any of said sources is written into any available empty payload field of any of said frames for transmitting data from each of said sources at its own desired bit rate via said bit stream and for transmitting data from said plurality of sources simultaneously via said bit stream.	The ATM SONET framing chips insert into the payload fields of the frames data in packetized format (ATM cells) from a plurality of sources in place of the idle cell bytes. Packets are inserted into the payload fields on a first-come-first-served basis whereby any packet from any source can occupy any available payload field in any frame. This transmits the source data at its own desired bit rate and transmits data from plural sources via the bit stream.
	* When properly equipped, such Lucent products include CBX-500 (wherein the ATM SONET framing chip is a "S/UNI" framing chip with a model number of S/UNI-155-Dual or other ATM-over-SONET framing chip), GX-550, the PSAX Gateway products (including PSAX 1000, PSAX 1250, PSAX 2300, and PSAX 4500), CBX-3500, DDM 2000, SGSN, GGSN, AnyMedia Access System, AXC 2000, APX 1000, APX 8000, MAX TNT Universal Gateway, APX 8100, the Stinger family of products (including Stinger FS+, Stinger RT, Stinger LS, Stinger DSL, and Stinger MRT), Lucent Compact Switch, PacketStar AC 60, PacketStar PSAX 20, B-STDX 8000/9000, and TMX-880.

EXHIBIT 3

**IN THE UNITED STATES DISTRICT COURT
FOR THE DISTRICT OF DELAWARE**

TELCORDIA TECHNOLOGIES, INC.,)	
)	
Plaintiff,)	
v.)	Civil Action No. 04-876 GMS
)	
CISCO SYSTEMS, INC.,)	
)	
Defendant.)	

**TELCORDIA TECHNOLOGIES, INC.'S SEVENTH SUPPLEMENTAL
RESPONSE TO CISCO'S FIRST SET OF INTERROGATORIES**

Plaintiff Telcordia Technologies, Inc. ("Telcordia") objects and responds to Defendant Cisco Systems, Inc.'s First Set of Interrogatories (Nos. 1-14) as follows:

GENERAL OBJECTIONS

1. Telcordia Technologies, Inc. ("Telcordia") objects to each interrogatory to the extent it seeks to require Telcordia to answer on behalf of any other person or entity. Telcordia responds to these interrogatories on its own behalf only.
2. Telcordia objects to each definition, instruction, and interrogatory to the extent it would require Telcordia to respond beyond that required by the Federal Rules of Civil Procedure or this Court's Local Rules.
3. Telcordia objects to Cisco's interrogatories to the extent they seek third-party information in Telcordia's possession, custody, or control that is subject to agreement, court order, or other duty preventing disclosure to Cisco. Telcordia objects to responding to propounded interrogatories that require the disclosure of trade secrets or other proprietary and confidential information of third parties unless Telcordia receives permission to disclose such

*Contains Telcordia, Cisco, and PMC-Sierra Confidential Information
Subject to Protective Order*

Because Cisco has possession, custody or control of the information regarding the design, operation, and manufacturing of its products that has not yet been produced to Telcordia, Telcordia is unable to identify persons with first-hand knowledge of the design, operation, or manufacturing of and to identify any documentation related to such design, operation, or manufacturing of the above-named accused products. Based upon information currently available to it, Telcordia notes that Cisco's website contains limited information concerning Cisco's products and activities.

INTERROGATORY NO. 3:

For each Claim-in-Suit, state in detail the basis for Telcordia's allegation of infringement, including without limitation, how each limitation of the claim is satisfied by each product, service, act or other instrumentality identified in response to Interrogatory No. 1, and whether the alleged infringement is literal, under the doctrine of equivalents, or both.

SIXTH SUPPLEMENTAL RESPONSE:²

Telcordia incorporates by reference each of the applicable general objections as though fully set forth herein. Telcordia objects to this interrogatory as unduly burdensome to the extent it prematurely seeks the disclosure of information, such as claim charts and claim constructions, at this early stage of discovery and prior to a time set for disclosure of such information by a court scheduling order or by a schedule set by the mutual agreement of the parties. Telcordia objects to this interrogatory as premature to the extent discovery of Cisco's documents, materials, and information is needed to respond. Telcordia objects to this interrogatory to the extent it seeks information that is protected by the attorney-client privilege or by the attorney work product immunity. Telcordia objects to this interrogatory to the extent it is duplicative of Interrogatory Nos. 1 and 2.

² Due to time constraints, Telcordia has not eliminated from its response products which have been removed from the case.

Pursuant to an agreement between the parties, the discovery requests of both Cisco and Telcordia that are directed to the '306 patent and/or the '633 patent, or to the "Patents-In-Suit," shall be interpreted to cover not only the '306 patent and/or the '633 patent, but also the '763 patent. Telcordia's supplementation of this interrogatory with information regarding the '763 patent incorporates and is subject to all of the General and Specific Objections already asserted as to this interrogatory.

Subject to and without waiving any of these general and specific objections and reserving its right to supplement its response as discovery proceeds, Telcordia responds to this interrogatory as follows:

Telcordia herein incorporates its objections and responses to Interrogatory No. 1 and 2.

Because Cisco has possession, custody or control of the information regarding the design, operation, and manufacturing of its products that it has not yet produced to Telcordia, Telcordia reserves the right to update its response to this interrogatory as discovery proceeds.

'306 Patent

Cisco's products that map packetized data into SONET frames, as identified in Telcordia's response to Interrogatory No. 1 and 2 literally infringe at least claims 1, 3, and 4 of the '306 patent as shown in the following chart by way of example, subject to updating (e.g., as to further claims and further products) as discovery proceeds and as claim language is construed by this Court:

<u>Claim 1, '306 Patent</u>	<u>Cisco Products with ATM SONET Framing Chips*</u>
1. A method for simultaneously transmitting data from sources having different bit rates in a telecommunication network comprising the steps of:	The Cisco Products transmit ATM cells containing data from sources having different bit rates.
generating a bit stream comprising a	The ATM SONET framing chips in the Cisco

<u>Claim 1, '306 Patent</u>	<u>Cisco Products with ATM SONET Framing Chips*</u>
sequence of frames, each of said frames including a transmission overhead field containing frame timing information and an empty payload field, and	Products generate a bit stream comprising a sequence of SONET frames, each frame including a transmission overhead field including A1, A2 frame timing bytes and an empty payload field containing "idle cell" bytes.
filling the empty payload fields in said frames with data in packetized format from a plurality of sources which have access to the bit stream including circuit or packet sources, such that data in packetized format from any of said sources is written into any available empty payload field of any of said frames for transmitting data from each of said sources at its own desired bit rate via said bit stream and for transmitting data from said plurality of sources simultaneously via said bit stream.	The ATM SONET framing chips insert into the payload fields of the frames data in packetized format (ATM cells) from a plurality of sources in place of the idle cell bytes. Packets are inserted into the payload fields on a first-come-first-served basis whereby any packet from any source can occupy any available payload field in any frame. This transmits the source data at its own desired bit rate and transmits data from plural sources via the bit stream.

Claim 1, '306 Patent	Cisco Products with ATM SONET Framing Chips*
	<p>*When properly equipped, such products include Cisco's Switching Products including the Catalyst 5000 series (including at least the 5000 and 5002 units), 5500 series (including at least the 5500, 5505, and 5509 units), Catalyst 6000 series (including at least the 6006 and 6009 units), Catalyst 6500 series (including at least the 6503, 6509, 6509-NEB, 6509-NEB-A, and 6513 units), Catalyst 8500 series (including at least the 8510 MSR, 8510 CSR, and 8540 MSR units), Lightstream 1010, Lightstream 2020, MGX 8200 series (including at least the MGX 8220, 8230, 8240, 8250, and 8260 units), MGX 8800 series (including at least the MGX 8830, 8850, and 8880 units), MGX 8900 series (including at least the MGX 8900 and 8950 units), IGX 8400 series (including at least the IGX 8410, IGX 8420, IGX 8430, and IGX 8450), BPX 8600 series (including at least the BPX 8620, BPX 8650, and BPX 8680); and Cisco's Router Products including at least the 2691, 3600 series (including at least the 3620, 3631, 3640, 3660, 3661, and 3662 units), 3700 series (including at least the 3725 and 3745 units), 3800 series (including at least the 3725 and 3745 units), Cisco 6000 series (including at least the 6015, 6130, 6160, 6260, 6701, 6705, and 6732 units), Cisco 7000 series (including at least the 7000 and 7010 units), 7100 series (including at least the 7120 and 7140 units and the Cisco uBR7100 Universal Broadband Router Series, including the uBR7111, 7111E, 7114, and 7114E units), 7200 series (including at least the 7202, 7204, 7204 VXR, 7206, and 7206 VXR units and the Cisco uBR7200 Universal Broadband Router Series, including the uBR7223, uBR7246, and uBR7246VXR units), 7300 series (including at least the 7301 and 7304 units), 7400 series (including at least the 7401 ASR unit), 7500 series (including at least the 7505, 7507, 7513, and 7576 units), 7600 series (including at least the 7603, 7604, 7606, 7609, and 7613), 10000 series (including at least the 10005, 10008, and 10720 units and the Cisco uBR10012 Universal Broadband Router), 12000 series (including at least the 12004, 12006, 12008, 12010, 12012, 12016, 12404, 12406, 12410, 12416, 12810, and 12816 units), and CRS-1, 6400 Broadband Concentrator, and 8110 Broadband Termination Unit.</p>

55 (Pages 214 to 217)

<p style="text-align: right;">214</p> <p>1 available empty payload field requirement of the 2 claims; is that correct?</p> <p>3 A. Well, what I concluded is that the SONET 4 framer is blind. The SONET framer that we've been 5 discussing here is blind to any priority scheme that 6 may exist among originating data sources if there, 7 in fact, were plural sources.</p> <p>8 Q. And that's the basis on which you conclude 9 that the accused products do not meet the available 10 empty payload field requirement, correct?</p> <p>11 MS. MEHTA: Objection. Misstates the 12 document.</p> <p>13 THE WITNESS: What I do state is that, 14 in the accused product, if there's any priority 15 scheme among different sources, if there is any, 16 that's considered before we get to the framer.</p> <p>17 BY MR. SMITH:</p> <p>18 Q. And you construe the claim construction 19 relating to available empty payload field as 20 requiring the priority to be determined within the 21 framer; is that correct?</p> <p>22 MS. MEHTA: Objection. Lack of</p>	<p style="text-align: right;">216</p> <p>1 sequence in which they'll be read onto the SONET 2 frames. So there's no way for this chip to assert 3 any priority.</p> <p>4 Q. Isn't the -- doesn't the mechanism of the 5 FIFO itself establish a priority? The first one in 6 has the priority of being the first one out, 7 correct?</p> <p>8 A. But I think that's the point. That was 9 given by the sequence in which the cells arrived 10 from the premultiplexer, if any. The FIFO cannot 11 reorder that. So this product cannot fill an empty 12 payload field with packet data from a source among 13 the plurality of sources of the highest priority 14 with a data packet ready to send. Those sources 15 somewhere else did or did not have data packets to 16 send. And based upon some prioritization scheme, if 17 any, in the source multiplexer, that sequence was 18 established. So that was done. That was a done 19 deed before the cells got to this chip.</p> <p>20 Q. So if the priority is established outside 21 the framer, it is your conclusion that the claim 22 limitation defined in paragraph 35 of the court's</p>
<p style="text-align: right;">215</p> <p>1 foundation. Mischaracterizes the testimony. And 2 vague.</p> <p>3 MR. CHERNY: I object to the 4 characterization of construing the construction.</p> <p>5 THE WITNESS: I applied the court's 6 claim construction to my analysis, and that 7 construction requires that an empty payload field 8 that can be filled with a data packet from the 9 source, among the plurality of sources, of the 10 highest priority with data, with a data packet ready 11 to transmit.</p> <p>12 BY MR. SMITH:</p> <p>13 Q. And that's not going on in this -- the 14 operation of this product here that we're 15 considering? Is that your conclusion?</p> <p>16 A. Well, if we focus specifically on Exhibit 17 Acampora 005, the block diagram appearing on Bates 18 page 476, the -- there is no way that I can 19 determine that this chip can resequence cells coming 20 from the cell FIFO. Cell FIFO outputs the chips. 21 It looks like it's a FIFO. It says first in/first 22 out. So whatever sequence they arrived in is the</p>	<p style="text-align: right;">217</p> <p>1 order cannot be met, correct?</p> <p>2 MS. MEHTA: Objection. Misstates the 3 testimony.</p> <p>4 THE WITNESS: What I did say is that 5 this chip, in my opinion, for the reasons stated, 6 cannot meet this claim limitation.</p> <p>7 BY MR. SMITH:</p> <p>8 Q. And the reason that you give is that the 9 priority of the cells is determined before the cells 10 enter the framer, correct?</p> <p>11 MS. MEHTA: Objection. Misstates the 12 testimony.</p> <p>13 THE WITNESS: What I said is that the 14 sequence of cells arriving to the FIFO already 15 reflect any prioritization that might have been 16 exercised by whatever device multiplexed the data 17 from the plurality of sources, assuming there were a 18 plurality of sources. There may have been one, in 19 which case it's a moot point.</p> <p>20 BY MR. SMITH:</p> <p>21 Q. Turn in page 4 to Bates page 676, please. 22 Do you see under the heading Traffic Management,</p>

efficiently making Layer 1 access decisions to partition out traffic to outlying internet protocol, GbE, ATM, fiber channel, or other Layer 2 switches. Localized Layer 2 functions such as routing and policy management are appropriately handled by the outlying switches while Layer 1 access switches provide high-speed performance IC-level switching/grooming of DWDM wavelengths [1].

4 OVERLAY NETWORKS

Today's data networks typically have four layers:

- IP for carrying applications
- ATM for traffic engineering
- SONET/SDH for transport
- DWDM for capacity

This architecture has been slow to scale, making it ineffective for photonic networks. Multilayering architectures typically suffer from the lowest common denominator effect where any one layer can limit the scalability of the other three layers and the entire network.

4.1 Two-Layer Networks Are Emerging

For the optical network developer, an absolute prerequisite for success is the ability to scale the network and deliver bit rate capacity where a customer needs it. Limitations of the existing network infrastructure are hindering movement to this service-delivery business model. It is the general belief in the industry that a new network foundation is required. This network foundation is seen as one that will easily adapt to support rapid change, growth, and highly responsive service delivery. What is needed is an intelligent, dynamic, photonic transport layer deployed in support of the service layer.

The photonic-network model divides the network into two domains: service and optical transport. The new architecture is seen as combining the benefits of photonic switching with advances in DWDM technology. It delivers a multigigabit bit rate capacity and provides wavelength-level traffic-engineered network interfaces to the service platforms. The service platform includes routers, ATM switches, and SONET/SDH add-drop multiplexers, which are redeployed from the transport layer to the service layer. The service layer is seen as relying completely on the photonic transport layer for the delivery of the necessary bit rate capacity where and when it is needed to peer nodes or to network elements (NEs). The bit rate capacity is provisioned in wavelength granularity rather than in PDH TDM granularities. We expect exponential growth rate of the fiber network; to meet these requirements, rapid provisioning is an integral part of the new architecture. While the first implementations of this model will support error detection, fault isolation, and restoration via SONET, these functions will gradually move to the optical layer.
